<p>Electrolysis is carried out at temp. 322 - 400°C while supplying steam to cathode chamber. Electric voltage in electrolyzing vessel is made minimum and the process becomes very economical. By restricting the electrolyzing temp. within the above range, the amt. of the steam dissolved in the fused NaOH is increased, thereby it becomes possible to use as the electrode an economical material, e.g. Ni etc.</p> <p>It is not necessary to supply the steam continuously, but the supply is carried-out intermittently. Heat loss is decreased, and corrosion of the electrolysis vessel is reduced. (4pp34).</p>	J54061088

Water is effectively and economically decomposed by electrolysis into H_2 and O_2 by carrying-out the electrolysis at 330 - 500°C while supplying steam to anode chamber by the use of sintered beta-alumina having an Na^+ mobility of 1, and of formula: Na_2O 0.5-11 Al_2O_3 , as the diaphragm, and fused $NaOH$ as the electrolyzing liquor, resp. As the electrode, Ni is suitably used due to its excellent anti-corrosive property against the fused $NaOH$. The mixing of O_2 and H_2 generated in both of the chambers through the diaphragm is completely prevented by the use of the beta-alumina diaphragm, thereby the electrolysis is carried-out economically without danger of explosion, and it becomes possible to bring both of the electrodes as close as possible to the diaphragm, thereby loss in electric voltage is made very low.(5pp34).

<p>Electrolysis cell for steam for hydrogen mfr. - uses metal oxide solid electrolyte and ruthenium, rhodium, palladium, silver, iridium, platinum and/or gold as electrodes</p>	<p>hydrogen gas atmosphere.(5ppw121).</p>
<p>(H3-0327-10) In an electrolysis cell used for electrolysis of steam and having the electrodes (2) arranged on both sides of a solid electrolyte (1), the improvement is that the solid electrolyte (1) is composed of metal oxide having the general formula AO_m-BO_n (wherein A is Zr; B is Hg, Ca, Y or rare earth metal; m and n are integers) and each of the electrodes is composed of metal selected from Ru, Rh, Pd, Ag, Ir, Pt and Au.</p>	
<p><u>USE/ADVANTAGE</u> Electrolysis of steam for produ. of hydrogen can be effected at a lower temp. and at high current efficiency.</p>	
<p><u>DETAILS</u> The cell contains an outer alumina pipe (3), an inner stainless steel pipe (4) and lead wires (5,6). The electrode (2) is pref. composed of Ag, and it can be produced e.g. by applying a vacuum vapour deposited Ag layer on the solid electrolyte surface; and then heat treating at 600°C. in a</p>	<p>J58034183</p>
